Principle - Layers of rock deposits with high intergranular and/or fracture permeability - usually providing a high level of water storage. They may support water supply and/or river base flow on a strategic scale.
Secondary A - Permeable layers capable of supporting water supplies at a local rather than strategic scale, and in some cases forming an important source of base flow to rivers.
Unproductive - Rock layers or drift deposits with low permeability that have negligible significance for water supply or river base flow.
